Dynamic subscription to YANG Events and Datastores over RESTCONF
draft-ietf-netconf-restconf-notif-14

Abstract

This document provides a RESTCONF binding to the dynamic subscription capability of both subscribed notifications and YANG-Push.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 12, 2019.

1. Introduction

Mechanisms to support event subscription and push are defined in
[I-D.draft-ietf-netconf-subscribed-notifications]. Enhancements to
[I-D.draft-ietf-netconf-subscribed-notifications] which enable YANG
datastore subscription and push are defined in
[I-D.ietf-netconf-yang-push]. This document provides a transport
specification for dynamic subscriptions over RESTCONF [RFC8040].
Requirements for these mechanisms are captured in [RFC7923].
The streaming of notifications encapsulating the resulting information push is done via the mechanism described in section 6.3 of [RFC8040].

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

The following terms use the definitions from [I-D.draft-ietf-netconf-subscribed-notifications]: dynamic subscription, event stream, notification message, publisher, receiver, subscriber, and subscription.

Other terms reused include datastore, which is defined in [RFC8342], and HTTP2 stream which maps to the definition of "stream" within [RFC7540], Section 2.

[ note to the RFC Editor - please replace XXXX within this document with the number of this document ]

3. Dynamic Subscriptions

This section provides specifics on how to establish and maintain dynamic subscriptions over RESTCONF [RFC8040]. Subscribing to event streams is accomplished in this way via RPCs defined within [I-D.draft-ietf-netconf-subscribed-notifications] Section 2.4. The RPCs are done via RESTCONF POSTs. YANG datastore subscription is accomplished via augmentations to [I-D.draft-ietf-netconf-subscribed-notifications] as described within [I-D.ietf-netconf-yang-push] Section 4.4.

As described in [RFC8040] Section 6.3, a GET needs to be made against a specific URI on the publisher. Subscribers cannot pre-determine the URI against which a subscription might exist on a publisher, as the URI will only exist after the "establish-subscription" RPC has been accepted. Therefore, the POST for the "establish-subscription" RPC replaces the GET request for the "location" leaf which is used in [RFC8040] to obtain the URI. The subscription URI will be determined and sent as part of the response to the "establish-subscription" RPC, and a subsequent GET to this URI will be done in order to start the flow of notification messages back to the subscriber. A subscription does not move to the active state as per Section 2.4.1. of [I-D.draft-ietf-netconf-subscribed-notifications] until the GET is received.
3.1. Transport Connectivity

For a dynamic subscription, where a RESTCONF session doesn’t already exist, a new RESTCONF session is initiated from the subscriber.

As stated in Section 2.1 of [RFC8040], a subscriber MUST establish the HTTP session over TLS [RFC8446] in order to secure the content in transit.

Without the involvement of additional protocols, HTTP sessions by themselves do not allow for a quick recognition of when the communication path has been lost with the publisher. Where quick recognition of the loss of a publisher is required, a subscriber SHOULD use a TLS heartbeat [RFC6520], just from subscriber to publisher, to track HTTP session continuity.

Loss of the heartbeat MUST result in any subscription related TCP sessions between those endpoints being torn down. A subscriber can then attempt to re-establish the dynamic subscription by using the procedure described in Section 3.4.

3.2. Discovery

Subscribers can learn what event streams a RESTCONF server supports by querying the "streams" container of ietf-subscribed-notification.yang in [I-D.ietf-netconf-subscribed-notifications]. Support for the "streams" container of ietf-restconf-monitoring.yang in [RFC8040] is not required. In the case when the RESTCONF binding specified by this document is used to convey the "streams" container from ietf-restconf-monitoring.yang (i.e., that feature is supported), any event streams contained therein are also expected to be present in the "streams" container of ietf-restconf-monitoring.yang.

Subscribers can learn what datastores a RESTCONF server supports by following Section 2 of [I-D.ietf-netconf-nmda-restconf].

3.3. RESTCONF RPCs and HTTP Status Codes

Specific HTTP responses codes as defined in [RFC7231] section 6 will indicate the result of RESTCONF RPC requests with the publisher. An HTTP status code of 200 is the proper response to any successful RPC defined within [I-D.ietf-netconf-subscribed-notifications] or [I-D.ietf-netconf-yang-push].

If a publisher fails to serve the RPC request for one of the reasons indicated in [I-D.ietf-netconf-subscribed-notifications] Section 2.4.6 or [I-D.ietf-netconf-yang-push] Appendix A, this will
be indicated by an appropriate error code, as shown below, transported in the HTTP response.

When an HTTP error code is returned, the RPC reply MUST include an "rpc-error" element per [RFC8040] Section 7.1 with the following parameter values:

- an "error-type" node of "application".
- an "error-tag" node with the value being a string that corresponds to an identity associated with the error. This "error-tag" will come from one of two places. Either it will correspond to the error identities within [I-D.draft-ietf-netconf-subscribed-notifications] section 2.4.6 for general subscription errors:

<table>
<thead>
<tr>
<th>error identity</th>
<th>uses error-tag</th>
<th>HTTP Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>dscp-unavailable</td>
<td>invalid-value</td>
<td>400</td>
</tr>
<tr>
<td>encoding-unsupported</td>
<td>invalid-value</td>
<td>400</td>
</tr>
<tr>
<td>filter-unsupported</td>
<td>invalid-value</td>
<td>400</td>
</tr>
<tr>
<td>insufficient-resources</td>
<td>resource-denied</td>
<td>409</td>
</tr>
<tr>
<td>no-such-subscription</td>
<td>invalid-value</td>
<td>404</td>
</tr>
<tr>
<td>replay-unsupported</td>
<td>operation-not-supported</td>
<td>501</td>
</tr>
</tbody>
</table>

Or this "error-tag" will correspond to the error identities within [I-D.ietf-netconf-yang-push] Appendix A.1 for subscription errors specific to YANG datastores:

<table>
<thead>
<tr>
<th>error identity</th>
<th>uses error-tag</th>
<th>HTTP Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>cant-exclude</td>
<td>operation-not-supported</td>
<td>501</td>
</tr>
<tr>
<td>datastore-not-subscribable</td>
<td>invalid-value</td>
<td>400</td>
</tr>
<tr>
<td>no-such-subscription-resync</td>
<td>invalid-value</td>
<td>404</td>
</tr>
<tr>
<td>on-change-unsupported</td>
<td>operation-not-supported</td>
<td>501</td>
</tr>
<tr>
<td>on-change-sync-unsupported</td>
<td>operation-not-supported</td>
<td>501</td>
</tr>
<tr>
<td>period-unsupported</td>
<td>invalid-value</td>
<td>400</td>
</tr>
<tr>
<td>update-too-big</td>
<td>too-big</td>
<td>400</td>
</tr>
<tr>
<td>sync-too-big</td>
<td>too-big</td>
<td>400</td>
</tr>
<tr>
<td>unchanging-selection</td>
<td>operation-failed</td>
<td>500</td>
</tr>
</tbody>
</table>

- an "error-app-tag" node with the value being a string that corresponds to an identity associated with the error, as defined in [I-D.draft-ietf-netconf-subscribed-notifications] section 2.4.6 for general subscriptions, and [I-D.ietf-netconf-yang-push] Appendix A.1, for datastore subscriptions. The tag to use depends on the RPC for which the error occurred. Viable errors for different RPCs are as follows:
Each error identity will be inserted as the "error-app-tag" using JSON encoding following the form <modulename>:<identityname>. An example of such a valid encoding would be "ietf-subscribed-notifications:no-such-subscription".

In case of error responses to an "establish-subscription" or "modify-subscription" request there is the option of including an "error-info" node. This node may contain hints for parameter settings that might lead to successful RPC requests in the future. Following are the yang-data structures which may be returned:

establish-subscription: returns hints in yang-data structure
---------------------- ------------------------------------
target: event stream   establish-subscription-stream-error-info
target: datastore      establish-subscription-datastore-error-info
modify-subscription: returns hints in yang-data structure
---------------------- ------------------------------------
target: event stream   modify-subscription-stream-error-info
target: datastore      modify-subscription-datastore-error-info

The yang-data included within "error-info" SHOULD NOT include the optional leaf "reason", as such a leaf would be redundant with information that is already placed within the "error-app-tag".

In case of an rpc error as a result of a "delete-subscription", a "kill-subscription", or a "resync-subscription" request, no "error-info" needs to be included, as the "subscription-id" is the only RPC input parameter and no hints regarding this RPC input parameters need to be provided.

Note that "error-path" [RFC8040] does not need to be included with the "rpc-error" element, as subscription errors are generally associated with the choice of RPC input parameters.
3.4. Call Flow for Server-Sent Events

The call flow for Server-Sent Events (SSE) is defined in Figure 1. The logical connections denoted by (a) and (b) can be a TCP connection or an HTTP2 stream (multiple HTTP2 streams can be carried in one TCP connection). Requests to [I-D.draft-ietf-netconf-subscribed-notifications] or [I-D.ietf-netconf-yang-push] augmented RPCs are sent on a connection indicated by (a). A successful "establish-subscription" will result in an RPC response returned with both a subscription identifier which uniquely identifies a subscription, as well as a URI which uniquely identifies the location of subscription on the publisher (b). This URI is defined via the "uri" leaf the Data Model in Section 7.

An HTTP GET is then sent on a separate logical connection (b) to the URI on the publisher. This signals the publisher to initiate the flow of notification messages which are sent in SSE [W3C-20150203] as a response to the GET. There can not be 2 or more simultaneous GET requests on a subscription URI: any GET request received while there is a current GET request on the same URI MUST be rejected with HTTP error code 409.

As described in [RFC8040] Section 6.4, RESTCONF servers SHOULD NOT send the "event" or "id" fields in the SSE event notifications.
RestCONF POST (RPC:establish-subscription)  
--------------------------------------------->  
HTTP 200 OK (ID,URI)  
<---------------------------------------------  
HTTP GET (URI)  
--------------------------------------------->  
HTTP 200 OK  
<---------------------------------------------  
SSE (notif-message)  
<---------------------------------------------  
RESTCONF POST (RPC:modify-subscription)  
--------------------------------------------->  
HTTP 200 OK  
<---------------------------------------------  
SSE (subscription-modified)  
<---------------------------------------------(c)  
SSE (notif-message)  
<---------------------------------------------  
RESTCONF POST (RPC:delete-subscription)  
--------------------------------------------->  
HTTP 200 OK  
<---------------------------------------------  
(a) (b)  
(a) (b)  

Figure 1: Dynamic with server-sent events

Additional requirements for dynamic subscriptions over SSE include:

- All subscription state notifications from a publisher MUST be returned in a separate SSE message used by the subscription to which the state change refers.

- Subscription RPCs MUST NOT use the connection currently providing notification messages for that subscription.

- In addition to an RPC response for a "modify-subscription" RPC traveling over (a), a "subscription-modified" state change notification MUST be sent within (b). This allows the receiver to know exactly when, within the stream of events, the new terms of
the subscription have been applied to the notification messages. See arrow (c).

- In addition to any required access permissions (e.g., NACM), RPCs modify-subscription, resync-subscription and delete-subscription SHOULD only be allowed by the same RESTCONF username [RFC8040] which invoked establish-subscription. Such a restriction generally serves to preserve users’ privacy, but exceptions might be made for administrators that may need to modify or delete other users’ subscriptions.

- The kill-subscription RPC can be invoked by any RESTCONF username with the required administrative permissions.

A publisher MUST terminate a subscription in the following cases:

- Receipt of a "delete-subscription" or a "kill-subscription" RPC for that subscription.

- Loss of TLS heartbeat

A publisher MAY terminate a subscription at any time as stated in [I-D.ietf-netconf-subscribed-notifications] Section 1.3

4. QoS Treatment

Qos treatment for event streams is described in [I-D.ietf-netconf-subscribed-notifications] Section 2.3. In addition, where HTTP2 transport is available to a notification message queued for transport to a receiver, the publisher MUST:

- take the "weighting" leaf node in [I-D.ietf-netconf-subscribed-notifications], and copy it into the HTTP2 stream weight, [RFC7540] section 5.3, and

- take any existing subscription "dependency", as specified by the "dependency" leaf node in [I-D.ietf-netconf-subscribed-notifications], and use the HTTP2 stream for the parent subscription as the HTTP2 stream dependency, [RFC7540] section 5.3.1, of the dependent subscription.

- set the exclusive flag, [RFC7540] section 5.3.1, to 0.

For dynamic subscriptions with the same DSCP value to a specific publisher, it is recommended that the subscriber sends all URI GET requests on a common HTTP2 session. Conversely, a subscriber can not
use a common HTTP2 session for subscriptions with different DSCP values.

5. Notification Messages

Notification messages transported over RESTCONF will be encoded according to [RFC8040], section 6.4.

6. YANG Tree

The YANG model defined in Section 7 has one leaf augmented into three places of [I-D.ietf-restconf-subscribed-notifications].

module: ietf-restconf-subscribed-notifications
  augment /sn:establish-subscription/sn:output:
    +--ro uri?   inet:uri
  augment /sn:subscriptions/sn:subscription:
    +--ro uri?   inet:uri
  augment /sn:subscription-modified:
    +--ro uri?   inet:uri

7. YANG module

This module references
[I-D.ietf-restconf-subscribed-notifications].

8. IANA Considerations

This document registers the following namespace URI in the "IETF XML
Registry" [RFC3688]:

Registrant Contact: The IESG.
XML: N/A; the requested URI is an XML namespace.

This document registers the following YANG module in the "YANG Module
Names" registry [RFC6020]:

Name: ietf-restconf-subscribed-notifications
Prefix: rsn
Reference: RFC XXXX: RESTCONF Transport for Event Notifications

9. Security Considerations

The YANG module specified in this document defines a schema for data
that is designed to be accessed via network management transports
such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF
layer is the secure transport layer, and the mandatory-to-implement
secure transport is Secure Shell (SSH) [RFC6242]. The lowest
RESTCONF layer is HTTPS, and the mandatory-to-implement secure
transport is TLS [RFC8446].
The one new data node introduced in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to this data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

Container: "/subscriptions"

- "uri": leaf will show where subscribed resources might be located on a publisher. Access control must be set so that only someone with proper access permissions, i.e., the same RESTCONF [RFC8040] user credentials which invoked the corresponding "establish-subscription", has the ability to access this resource.

The subscription URI is implementation specific and is encrypted via the use of TLS. Therefore, even if an attacker succeeds in guessing the subscription URI, a RESTCONF username [RFC8040] with the required administrative permissions must be used to be able to access or modify that subscription. It is recommended that the subscription URI values not be easily predictable.

The access permission considerations for the RPCs modify-subscription, resync-subscription, delete-subscription and kill-subscription are described in Section 3.4.

If a buggy or compromised RESTCONF subscriber sends a number of "establish-subscription" requests, then these subscriptions accumulate and may use up system resources. In such a situation, the publisher MAY also suspend or terminate a subset of the active subscriptions from that RESTCONF subscriber in order to reclaim resources and preserve normal operation for the other subscriptions.

10. Acknowledgments

We wish to acknowledge the helpful contributions, comments, and suggestions that were received from: Ambika Prasad Tripathy, Alberto Gonzalez Prieto, Susan Hares, Tim Jenkins, Balazs Lengyel, Kent Watsen, Michael Scharf, Guangying Zheng, Martin Bjorklund, Qin Wu and Robert Wilton.

11. References

11.1. Normative References

11.2. Informative References

[I-D. draft-ietf-netconf-netconf-event-notifications]

[I-D. draft-ietf-netconf-nmda-restconf]

Appendix A. Examples

This section is non-normative. To allow easy comparison, this section mirrors the functional examples shown with NETCONF over XML within [I-D.draft-ietf-netconf-netconf-event-notifications]. In addition, HTTP2 vs HTTP1.1 headers are not shown as the contents of the JSON encoded objects are identical within.

The subscription URI values used in the examples in this section are purely illustrative, and are not indicative of the expected usage which is described in Section 9.

The DSCP values are only for example purposes and are all indicated in decimal since the encoding is JSON [RFC7951].

A.1. Dynamic Subscriptions

A.1.1. Establishing Dynamic Subscriptions

The following figure shows two successful "establish-subscription" RPC requests as per [I-D.draft-ietf-netconf-subscribed-notifications]. The first request is given a subscription identifier of 22, the second, an identifier of 23.
Figure 2: Multiple subscriptions over RESTCONF/HTTP

To provide examples of the information being transported, example messages for interactions in Figure 2 are detailed below:

```
POST /restconf/operations
    /ietf-subscribed-notifications:establish-subscription

{
    "ietf-subscribed-notifications:input": {
        "stream-xpath-filter": "/example-module:foo/",
        "stream": "NETCONF",
        "dscp": 10
    }
}
```

Figure 3: establish-subscription request (a)
As publisher was able to fully satisfy the request, the publisher sends the subscription identifier of the accepted subscription, and the URI:

HTTP status code - 200

```json
{
  "id": 22,
  "uri": "https://example.com/restconf/subscriptions/22"
}
```

Figure 4: establish-subscription success (b)

Upon receipt of the successful response, the subscriber does a GET the provided URI to start the flow of notification messages. When the publisher receives this, the subscription is moved to the active state (c).

GET /restconf/subscriptions/22

Figure 5: establish-subscription subsequent POST

While not shown in Figure 2, if the publisher had not been able to fully satisfy the request, or subscriber has no authorization to establish the subscription, the publisher would have sent an RPC error response. For instance, if the "dscp" value of 10 asserted by the subscriber in Figure 3 proved unacceptable, the publisher may have returned:

HTTP status code - 400

```json
{ "ietf-restconf:errors" : { "error" : [ { "error-type": "application",
"error-tag": "invalid-value",
"error-severity": "error",
"error-app-tag": "ietf-subscribed-notifications:dscp-unavailable"
} ] }
}
```

Figure 6: an unsuccessful establish subscription
The subscriber can use this information in future attempts to establish a subscription.

A.1.2. Modifying Dynamic Subscriptions

An existing subscription may be modified. The following exchange shows a negotiation of such a modification via several exchanges between a subscriber and a publisher. This negotiation consists of a failed RPC modification request/response, followed by a successful one.

```
+------------+                 +-----------+
<p>| Subscriber |                 | Publisher |
|------------|                 |-----------|
|                              |</p>
<table>
<thead>
<tr>
<th>notification message (id#23)</th>
</tr>
</thead>
<tbody>
<tr>
<td>modify-subscription (id#23)</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>HTTP 400 error (with hint)</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>modify-subscription (id#23)</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>HTTP 200 OK</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>notif-mesg (id#23)</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
</tbody>
</table>
```

Figure 7: Interaction model for successful subscription modification

If the subscription being modified in Figure 7 is a datastore subscription as per [I-D.ietf-netconf-yang-push], the modification request made in (d) may look like that shown in Figure 8. As can be seen, the modifications being attempted are the application of a new xpath filter as well as the setting of a new periodic time interval.
POST /restconf/operations
   /ietf-subscribed-notifications:modify-subscription
{
   "ietf-subscribed-notifications:input": {
      "id": 23,
      "ietf-yang-push:datastore-xpath-filter": 
        "/example-module:foo/example-module:bar",
      "ietf-yang-push:periodic": {
         "ietf-yang-push:period": 500
      }
   }
}

Figure 8: Subscription modification request (c)

If the publisher can satisfy both changes, the publisher sends a positive result for the RPC. If the publisher cannot satisfy either of the proposed changes, the publisher sends an RPC error response (e). The following is an example RPC error response for (e) which includes a hint. This hint is an alternative time period value which might have resulted in a successful modification:

HTTP status code - 400

{ "ietf-restconf:errors": {
   "error": {
      "error-type": "application",
      "error-tag": "invalid-value",
      "error-severity": "error",
      "error-app-tag": "ietf-yang-push:period-unsupported",
      "error-info": {
         "ietf-yang-push":
           "modify-subscription-datastore-error-info": {
              "period-hint": 3000
           }
      }
   }
}

Figure 9: Modify subscription failure with Hint (e)
A.1.3. Deleting Dynamic Subscriptions

The following demonstrates deleting a subscription. This subscription may have been to either a stream or a datastore.

POST /restconf/operations
    /ietf-subscribed-notifications:delete-subscription

    {
        "delete-subscription": {
            "id": "22"
        }
    }

Figure 10: Delete subscription

If the publisher can satisfy the request, the publisher replies with success to the RPC request.

If the publisher cannot satisfy the request, the publisher sends an error-rpc element indicating the modification didn’t work. Figure 11 shows a valid response for existing valid subscription identifier, but that subscription identifier was created on a different transport session:

HTTP status code - 404

    {
        "ietf-restconf:errors": {
            "error": [
                "error-type": "application",
                "error-tag": "invalid-value",
                "error-severity": "error",
                "error-app-tag":
                    "ietf-subscribed-notifications:no-such-subscription"
            ]
        }
    }

Figure 11: Unsuccessful delete subscription

A.2. Subscription State Notifications

A publisher will send subscription state notifications according to the definitions within [I-D.draft-ietf-netconf-subscribed-notifications]).
A.2.1. subscription-modified

A "subscription-modified" encoded in JSON would look like:

```json
{
   "ietf-restconf:notification": {
      "eventTime": "2007-09-01T10:00:00Z",
      "ietf-subscribed-notifications:subscription-modified": {
         "id": 39,
         "uri": "https://example.com/restconf/subscriptions/22",
         "stream": {
            "ietf-netconf-subscribed-notifications": "NETCONF"
         }
      }
   }
}
```

Figure 12: subscription-modified subscription state notification

A.2.2. subscription-completed, subscription-resumed, and replay-complete

A "subscription-completed" would look like:

```json
{
   "ietf-restconf:notification": {
      "eventTime": "2007-09-01T10:00:00Z",
      "ietf-subscribed-notifications:subscription-completed": {
         "id": 39
      }
   }
}
```

Figure 13: subscription-completed notification in JSON

The "subscription-resumed" and "replay-complete" are virtually identical, with "subscription-completed" simply being replaced by "subscription-resumed" and "replay-complete".

A.2.3. subscription-terminated and subscription-suspended

A "subscription-terminated" would look like:
The "subscription-suspended" is virtually identical, with "subscription-terminated" simply being replaced by "subscription-suspended".

A.3. Filter Example

This section provides an example which illustrate the method of filtering event record contents. The example is based on the YANG notification "vrrp-protocol-error-event" as defined per the ietf-vrrp.yang module within [RFC8347]. Event records based on this specification which are generated by the publisher might appear as:

```json
{  
    "ietf-restconf:notification": {  
        "eventTime": "2018-09-14T08:22:33.44Z",  
        "ietf-vrrp:vrrp-protocol-error-event": {  
            "protocol-error-reason": "checksum-error"  
        }
    }
}
```

Figure 15: RFC 8347 (VRRP) - Example Notification

Suppose a subscriber wanted to establish a subscription which only passes instances of event records where there is a "checksum-error" as part of a VRRP protocol event. Also assume the publisher places such event records into the NETCONF stream. To get a continuous series of matching event records, the subscriber might request the application of an XPath filter against the NETCONF stream. An "establish-subscription" RPC to meet this objective might be:
POST /restconf/operations
   /ietf-subscribed-notifications:establish-subscription
{
   "ietf-subscribed-notifications:input": {
      "stream": "NETCONF",
      "stream-xpath-filter": "/ietf-vrrp:vrrp-protocol-error-event[
         protocol-error-reason='checksum-error']/",
   }
}

Figure 16: Establishing a subscription error reason via XPath

For more examples of XPath filters, see [XPATH].

Suppose the "establish-subscription" in Figure 16 was accepted. And suppose later a subscriber decided they wanted to broaden this subscription cover to all VRRP protocol events (i.e., not just those with a "checksum error"). The subscriber might attempt to modify the subscription in a way which replaces the XPath filter with a subtree filter which sends all VRRP protocol events to a subscriber. Such a "modify-subscription" RPC might look like:

POST /restconf/operations
   /ietf-subscribed-notifications:modify-subscription
{
   "ietf-subscribed-notifications:input": {
      "stream": "NETCONF",
      "stream-subtree-filter": {
         "/ietf-vrrp:vrrp-protocol-error-event" : {}  
      }
   }
}

Figure 17

For more examples of subtree filters, see [RFC6241], section 6.4.

Appendix B. Changes between revisions

   (To be removed by RFC editor prior to publication)

   v13 - v14

   o Addressed review comments from IESG.

   v12 - v13
- Enhanced "error-tag" values based on SN review.

v11 - v12
- Added text in 3.2 for expected behavior when ietf-restconf-monitoring.yang is also supported.
- Added section 2 to the reference to draft-ietf-netconf-nmda-restconf.
- Replaced kill-subscription-error by delete-subscription-error in section 3.3.
- Clarified vertical lines (a) and (b) in Figure 1 of section 3.4
- Section 3.4, 3rd bullet after Figure 1, replaced "must" with "MUST".
- Modified text in section 3.4 regarding access to RPCs modify-subscription, resync-subscription, delete-subscription and kill-subscription.
- Section 4, first bullet for HTTP2: replaced dscp and priority with weighting and weight.
- Section 6, added YANG tree diagram and fixed description of the module.
- Section 7, fixed indentation of module description statement.
- Section 7, in YANG module changed year in copyright statement to 2019.
- Section 8, added text on how server protects access to the subscription URI.
- Fixed outdated references and removed unused references.
- Fixed the instances of line too long.
- Fixed example in Figure 3.

v10 - v11
- Per Kent’s request, added name attribute to artwork which need to be extracted

v09 - v10
- Fixed typo for resync.
- Added text wrt RPC permissions and RESTCONF username.

**v08 - v09**

- Addressed comments received during WGLC.

**v07 - v08**

- Aligned with RESTCONF mechanism.
- YANG model: removed augment of subscription-started, added restconf transport.
- Added Appendix A.3 for filter example.

**v06 - v07**

- Removed configured subscriptions.
- Subscription identifier renamed to id.

**v05 - v06**

- JSON examples updated by Reshad.

**v04 - v05**

- Error mechanisms updated to match embedded RESTCONF mechanisms
- Restructured format and sections of document.
- Added a YANG data model for HTTP specific parameters.
- Mirrored the examples from the NETCONF transport draft to allow easy comparison.

**v03 - v04**

- Draft not fully synched to new version of subscribed-notifications yet.
- References updated
v02 - v03
  o Event notification reframed to notification message.
  o Tweaks to wording/capitalization/format.

v01 - v02
  o Removed sections now redundant with
    [I-D.draft-ietf-netconf-subscribed-notifications] and
    [I-D.ietf-netconf-yang-push] such as: mechanisms for subscription
    maintenance, terminology definitions, stream discovery.
  o 3rd party subscriptions are out-of-scope.
  o SSE only used with RESTCONF and HTTP1.1 dynamic subscriptions
  o Timeframes for event tagging are self-defined.
  o Clean-up of wording, references to terminology, section numbers.

v00 - v01
  o Removed the ability for more than one subscription to go to a
    single HTTP2 stream.
  o Updated call flows. Extensively.
  o SSE only used with RESTCONF and HTTP1.1 dynamic subscriptions
  o HTTP is not used to determine that a receiver has gone silent and
    is not Receiving Event Notifications
  o Many clean-ups of wording and terminology
