Host Resources MIB

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. This memo obsoletes RFC 1514, the "Host Resources MIB". This memo extends that specification by clarifying changes based on implementation and deployment experience and documenting the Host Resources MIB in SMIv2 format while remaining semantically identical to the existing SMIv1-based MIB.

This memo defines a MIB for use with managing host systems. The term "host" is construed to mean any computer that communicates with other similar computers attached to the internet and that is directly used by one or more human beings. Although this MIB does not necessarily apply to devices whose primary function is communications services (e.g., terminal servers, routers, bridges, monitoring equipment), such relevance is not explicitly precluded. This MIB instruments attributes common to all internet hosts including, for example, both personal computers and systems that run variants of Unix.
1. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- An overall architecture, described in RFC 2571 [RFC2571].

- Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIv1 and described in STD 16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215 [RFC1215]. The second version, called SMIv2, is described in STD 58, RFC 2578 [RFC2578], RFC 2579 [RFC2579] and RFC 2580 [RFC2580].

- Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [RFC1157]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [RFC1901] and RFC 1906 [RFC1906]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [RFC1906], RFC 2572 [RFC2572] and RFC 2574 [RFC2574].
Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [RFC1157]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [RFC1905].

A set of fundamental applications described in RFC 2573 [RFC2573] and the view-based access control mechanism described in RFC 2575 [RFC2575].

A more detailed introduction to the current SNMP Management Framework can be found in RFC 2570 [RFC2570].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIv2. A MIB conforming to the SMIv1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIv2 will be converted into textual descriptions in SMIv1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

2. Host Resources MIB

The Host Resources MIB defines a uniform set of objects useful for the management of host computers. Host computers are independent of the operating system, network services, or any software application.

The Host Resources MIB defines objects which are common across many computer system architectures.

In addition, there are objects in the SNMPv2-MIB [RFC1907] and IF-MIB [RFC2233] which also provide host management functionality. Implementation of the System and Interfaces groups is mandatory for implementors of the Host Resources MIB.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].
3. IANA Considerations

This MIB contains type definitions for storage types, device types, and file system types for use as values for the hrStorageType, hrDeviceType, and hrFSType objects, respectively. As new computing technologies are developed, new types need to be registered for these technologies. The IANA (Internet Assigned Numbers Authority) is designated as the registration authority for new registrations beyond those published in this document. The IANA will maintain the HOST-RESOURCES-TYPES module as new registrations are added and publish new versions of this module.

Given the large number of such technologies and potential confusion in naming of these technologies (such as a technology known by two names or a name and an acronym), there is a real danger that more than one registration might be created for what is essentially the same technology. In order to ensure that future type registrations are performed correctly, applications for new types will be reviewed by a Designated Expert appointed by the IESG.

In addition, the Host Resources MIB mailing list is dedicated to discussion of this MIB. To join the mailing list, send a request message to hostmib-request@andrew.cmu.edu. The mailing list address is hostmib@andrew.cmu.edu.

DESCRIPTION
"This MIB is for use in managing host systems. The term 'host' is construed to mean any computer that communicates with other similar computers attached to the internet and that is directly used by one or more human beings. Although this MIB does not necessarily apply to devices whose primary function is communications services (e.g., terminal servers, routers, bridges, monitoring equipment), such relevance is not explicitly precluded. This MIB instruments attributes common to all internet hosts including, for example, both personal computers and systems that run variants of Unix."

REVISION "200003060000Z" -- 6 March 2000

DESCRIPTION
"Clarifications and bug fixes based on implementation experience. This revision was also reformatted in the SMIv2 format. The revisions made were:

New RFC document standards:
  Added Copyright notice, updated introduction to SNMP Framework, updated references section, added reference to RFC 2119, and added a meaningful Security Considerations section.

New IANA considerations section for registration of new types

Conversion to new SMIv2 syntax for the following types and macros:
  Counter32, Integer32, Gauge32, MODULE-IDENTITY, OBJECT-TYPE, TEXTUAL-CONVENTION, OBJECT-IDENTITY, MODULE-COMPLIANCE, OBJECT-GROUP

Used new Textual Conventions:
  TruthValue, DateAndTime, AutonomousType, InterfaceIndexOrZero

Fixed typo in hrPrinterStatus.

Added missing error bits to hrPrinterDetectedErrorState and clarified confusion resulting from suggested mappings to hrPrinterStatus."
Clarified that size of objects of type InternationalDisplayString is number of octets, not number of encoded symbols.

Clarified the use of the following objects based on implementation experience:
- hrSystemInitialLoadDevice
- hrSystemInitialLoadParameters
- hrMemorySize
- hrStorageSize
- hrStorageAllocationFailures
- hrDeviceErrors
- hrProcessorLoad
- hrNetworkIfIndex
- hrDiskStorageCapacity
- hrSWRunStatus
- hrSWRunPerfCPU
- hrSWInstalledDate

Clarified implementation technique for hrSWInstalledTable.

Used new AUGMENTS clause for hrSWRunPerfTable.

Added Internationalization Considerations section.

This revision published as RFC2790."

REVISION "9910202200Z"    -- 20 October, 1999
DESCRIPTION
"The original version of this MIB, published as RFC1514."
 ::= { hrMIBAdminInfo 1 }
manufacturer, model, and version of a specific hardware or software product. It is suggested that these OBJECT IDENTIFIERS are allocated such that all products from a particular manufacturer are registered under a subtree distinct to that manufacturer. In addition, all versions of a product should be registered under a subtree distinct to that product. With this strategy, a management station may uniquely determine the manufacturer and/or model of a product whose productID is unknown to the management station. Objects of this type may be useful for inventory purposes or for automatically detecting incompatibilities or version mismatches between various hardware and software components on a system.

For example, the product ID for the ACME 4860 66MHz clock doubled processor might be:
enterprises.acme.acmeProcessors.a4860DX2.MHz66

A software product might be registered as:
enterprises.acme.acmeOperatingSystems.acmeDOS.six(6).one(1)

SYNTAX OBJECT IDENTIFIER
-- unknownProduct will be used for any unknown ProductID
-- unknownProduct OBJECT IDENTIFIER ::= { 0 0 }

InternationalDisplayString ::= TEXTUAL-CONVENTION
STATUS current
DESCRIPTION
"This data type is used to model textual information in some character set. A network management station should use a local algorithm to determine which character set is in use and how it should be displayed. Note that this character set may be encoded with more than one octet per symbol, but will most often be NVT ASCII. When a size clause is specified for an object of this type, the size refers to the length in octets, not the number of symbols."

SYNTAX OCTET STRING
-- The Host Resources System Group

hrSystemUptime OBJECT-TYPE
SYNTAX     TimeTicks
MAX-ACCESS read-only
STATUS     current
DESCRIPTION
"The amount of time since this host was last initialized. Note that this is different from sysUpTime in the SNMPv2-MIB [RFC1907] because sysUpTime is the uptime of the network management portion of the system."

MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"The (conceptual) table of logical storage areas on
the host.

An entry shall be placed in the storage table for each
logical area of storage that is allocated and has
fixed resource limits. The amount of storage
represented in an entity is the amount actually usable
by the requesting entity, and excludes loss due to
formatting or file system reference information.

These entries are associated with logical storage
areas, as might be seen by an application, rather than
physical storage entities which are typically seen by
an operating system. Storage such as tapes and
floppies without file systems on them are typically
not allocated in chunks by the operating system to
requesting applications, and therefore shouldn’t
appear in this table. Examples of valid storage for
this table include disk partitions, file systems, ram
(for some architectures this is further segmented into
regular memory, extended memory, and so on), backing
store for virtual memory (‘swap space’).

This table is intended to be a useful diagnostic for
‘out of memory’ and ‘out of buffers’ types of
failures. In addition, it can be a useful performance
monitoring tool for tracking memory, disk, or buffer
usage."

MAX-ACCESS read-only
STATUS current
DESCRIPTION "The product ID for this device."
 ::= { hrDeviceEntry 4 }

hrDeviceStatus OBJECT-TYPE
SYNTAX INTEGER {
  unknown(1),
  running(2),
  warning(3),
  testing(4),
  down(5)
The current operational state of the device described by this row of the table. A value unknown(1) indicates that the current state of the device is unknown. running(2) indicates that the device is up and running and that no unusual error conditions are known. The warning(3) state indicates that agent has been informed of an unusual error condition by the operational software (e.g., a disk device driver) but that the device is still 'operational'. An example would be a high number of soft errors on a disk. A value of testing(4), indicates that the device is not available for use because it is in the testing state. The state of down(5) is used only when the agent has been informed that the device is not available for any use.

hrDeviceErrors OBJECT-TYPE
SYNTAX Counter32
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The number of errors detected on this device. It should be noted that as this object has a SYNTAX of Counter32, that it does not have a defined initial value. DESCRIPTION
"The current status of this printer device."
::= { hrPrinterEntry 1 }

hrPrinterDetectedErrorState OBJECT-TYPE
SYNTAX OCTET STRING
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"This object represents any error conditions detected by the printer. The error conditions are encoded as bits in an octet string, with the following definitions:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Bit #</th>
</tr>
</thead>
<tbody>
<tr>
<td>lowPaper</td>
<td>0</td>
</tr>
</tbody>
</table>
noPaper 1
lowToner 2
noToner 3
doorOpen 4
jammed 5
offline 6
serviceRequested 7
inputTrayMissing 8
outputTrayMissing 9
markerSupplyMissing 10
outputNearFull 11
outputFull 12
inputTrayEmpty 13
overduePreventMaint 14

Bits are numbered starting with the most significant bit of the first byte being bit 0, the least significant bit of the first byte being bit 7, the most significant bit of the second byte being bit 8, and so on. A one bit encodes that the condition was detected, while a zero bit encodes that the condition was not detected.

This object is useful for alerting an operator to specific warning or error conditions that may occur, especially those requiring human intervention.

6. Internationalization Considerations

This MIB has many objects that identify file-system pathnames on the
managed host. Many file systems allow pathnames to be encoded in a
variety of character sets (other than ASCII), but do not support the
encoding of the actual character set used with the pathname. The
implementation strategy is that user interfaces (i.e. character-based
shells or graphical applications) will have configuration options
that control with which character set they will interpret and display
all pathnames. This is often a per-user configuration (e.g. an
environment variable), so that users using different languages and
character sets on a multi-user system may each work effectively with
their preferred character set. A human usually controls this
configuration. If an application is not configured or is configured
incorrectly, it will often have trouble displaying pathnames in the
intended character set.

This situation made it important for this MIB to handle two issues:

1) Pathname objects must be able to transfer a variety of character
   sets with potentially multi-byte encodings; and,
2) HostMIB agents will generally not be correctly configured for the appropriate character set to be used for all files on the system, particularly on a system with multiple users using different character sets. It was thus impossible to mandate that the agent tag pathnames with the character set in use.

These issues were solved with the introduction of the InternationalDisplayString textual convention, which supports multi-byte encodings. Network management stations should use a local algorithm to determine which character set is in use and how it should be displayed. It is expected that network management station applications will rely on human configuration to choose which character set in which to interpret InternationalDisplayString objects, much like an application running locally on that host.

7. Security Considerations

There are a number of management objects defined in this MIB that have a MAX-ACCESS clause of read-write. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on system operations.

There are a number of managed objects in this MIB that may contain sensitive information. The objects in the Running Software Group list information about running software on the system (including the operating system software and version). Some may wish not to disclose to others what software they are running. Further, an inventory of the running software and versions may be helpful to an attacker who hopes to exploit software bugs in certain applications. The same issues exist for the objects in the Installed Software Group.

It is thus important to control even GET access to these objects and possibly to even encrypt the values of these object when sending them over the network via SNMP. Not all versions of SNMP provide features for such a secure environment.

SNMPv1 by itself is not a secure environment. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB.

It is recommended that the implementers consider the security features as provided by the SNMPv3 framework. Specifically, the use of the User-based Security Model RFC 2574 [RFC2574] and the View-based Access Control Model RFC 2575 [RFC2575] is recommended.
It is then a customer/user responsibility to ensure that the SNMP entity giving access to an instance of this MIB, is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
