A YANG Data Model for System Management

Abstract

This document defines a YANG data model for the configuration and identification of some common system properties within a device containing a Network Configuration Protocol (NETCONF) server. This document also includes data node definitions for system identification, time-of-day management, user management, DNS resolver configuration, and some protocol operations for system management.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc7317.

Copyright Notice

This document is subject to BCP 78 and the IETF Trust’s Legal Provisions Relating to IETF Documents (http://trustee.ietf.org/license-info) in effect on the date of publication of this document. Please review these documents carefully, as they describe your rights and restrictions with respect to this document. Code Components extracted from this document must include Simplified BSD License text as described in Section 4.e of the Trust Legal Provisions and are provided without warranty as described in the Simplified BSD License.
1. Introduction

This document defines a YANG [RFC6020] data model for the configuration and identification of some common properties within a device containing a Network Configuration Protocol (NETCONF) server.

Devices that are managed by NETCONF and perhaps other mechanisms have common properties that need to be configured and monitored in a standard way.

The "ietf-system" YANG module defined in this document provides the following features:

- configuration and monitoring of system identification
- configuration and monitoring of system time-of-day
- configuration of user authentication
o configuration of local users

o configuration of the DNS resolver

o system control operations (shutdown, restart, setting time)

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, [RFC2119].

The following terms are defined in [RFC6241] and are not redefined here:

- client
- configuration data
- server
- state data

The following terms are defined in [RFC6020] and are not redefined here:

- augment
- data model

1.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

- Brackets "[" and "]" enclose list keys.

- Abbreviations before data node names: "rw" means configuration (read-write), and "ro" means state data (read-only).

- Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").

o Ellipsis ("...") stands for contents of subtrees that are not shown.

2. Objectives

2.1. System Identification

There are many common properties used to identify devices, operating systems, software versions, etc. that need to be supported in the system data module. These objects are defined as operational state data, and the information returned by the server is intended to be specific to the device vendor.

Some user-configurable administrative strings are also provided, such as the system location and description.

2.2. System Time Management

Management of the date and time used by the system needs to be supported. The use of one or more NTP servers to automatically set the system date and time needs to be possible. Utilization of the Time Zone Database [RFC6557] also needs to be supported. It should be possible to configure the system to use NTP.

2.3. User Authentication

The authentication mechanism needs to support password authentication over RADIUS in order to support deployment scenarios with centralized authentication servers. Additionally, for scenarios when no centralized authentication server exists or for situations where the centralized authentication server cannot be reached from the device, local users need to be supported.

Since the mandatory transport protocol for NETCONF is Secure Shell (SSH) [RFC6242], the authentication model needs to support SSH’s "publickey" and "password" authentication methods [RFC4252].

The model for authentication configuration should be flexible enough to support authentication methods defined by other standards documents or by vendors. It should be possible to configure the system authentication properties.
2.4. DNS Resolver

The configuration of the DNS resolver within the system containing the NETCONF server is required in order to control how domain names are resolved.

2.5. System Control

A few operations are needed to support common tasks such as restarting the device or setting the system date and time.

3. System Data Model

3.1. System Identification

The data model for system identification has the following structure:

```
---rw system
 |    ---rw contact?    string
 |    ---rw hostname?   inet:domain-name
 |    ---rw location?   string
    ---ro system-state
     ---ro platform
      ---ro os-name?    string
      ---ro os-release? string
      ---ro os-version? string
      ---ro machine?    string
```
3.2. System Time Management

The data model for system time management has the following structure:

```
  +--rw system
       +--rw clock
          |  +--rw (timezone)?
          |     +--:(timezone-name)
          |     |  +--rw timezone-name? timezone-name
          |     |     +--rw timezone-utc-offset? int16
          |     +--rw ntp!
          |     +--rw enabled? boolean
          |     +--rw server* [name]
          |        +--rw name string
          |        +--rw (transport)
          |        |  +--:(udp)
          |        |     +--rw udp
          |        |     |  +--rw address inet:host
          |        |     |     +--rw port? inet:port-number
          |        |     +--rw association-type? enumeration
          |        |     +--rw iburst? boolean
          |        |     +--rw prefer? boolean
          +--ro system-state
              +--ro clock
              |  +--ro current-datetime? yang:date-and-time
              |  +--ro boot-datetime? yang:date-and-time
```

New "case" statements can be added in future revisions of this data model, or through augmentation by some other data model.
3.3. DNS Resolver Model

The data model for configuration of the DNS resolver has the following structure:

```
+--rw system
  +--rw dns-resolver
    +--rw search* inet:domain-name
    +--rw server* [name]
      +--rw name string
      +--rw (transport)
        +--:(udp-and-tcp)
          +--udp-and-tcp
            +--rw address inet:ip-address
            +--rw port? inet:port-number
    +--rw options
      +--rw timeout? uint8
      +--rw attempts? uint8
```

New "case" statements can be added in future revisions of this data model, or through augmentation by some other data model.

3.4. RADIUS Client Model

The data model for configuration of the RADIUS client has the following structure:

```
+--rw system
  +--rw radius
    +--rw server* [name]
      +--rw name string
      +--rw (transport)
        +--:(udp)
          +--rw udp
            +--rw address inet:host
            +--rw authentication-port? inet:port-number
            +--rw shared-secret string
          +--rw authentication-type? identityref
    +--rw options
      +--rw timeout? uint8
      +--rw attempts? uint8
```

New "case" statements can be added in future revisions of this data model, or through augmentation by some other data model.
3.5. User Authentication Model

This document defines three authentication methods for use with NETCONF:

- publickey for local users over SSH
- password for local users over any secure transport
- password for RADIUS users over any secure transport

Additional methods can be defined by other standards documents or by vendors.

This document defines two optional YANG features: "local-users" and "radius-authentication", which the server advertises to indicate support for configuring local users on the device and support for using RADIUS for authentication, respectively.

The authentication parameters defined in this document are primarily used to configure authentication of NETCONF users but MAY also be used by other interfaces, e.g., a command line interface or a web-based user interface.

The data model for user authentication has the following structure:

```
+--rw system
    +--rw authentication
        +--rw user-authentication-order* identityref
        +--rw user* [name]
            +--rw name string
            +--rw password? ianach:crypt-hash
            +--rw authorized-key* [name]
                +--rw name string
                +--rw algorithm string
                +--rw key-data binary
```

3.5.1. SSH Public Key Authentication

If the NETCONF server advertises the "local-users" feature, configuration of local users and their SSH public keys is supported in the /system/authentication/user list.

Public key authentication is requested by the SSH client. If the "local-users" feature is supported, then when a NETCONF client starts an SSH session towards the server using the "publickey" authentication "method name" [RFC4252], the SSH server looks up the
user name given in the SSH authentication request in the
/system/authentication/user list and verifies the key as described in
[RFC4253].

3.5.2. Local User Password Authentication

If the NETCONF server advertises the "local-users" feature,
configuration of local users and their passwords is supported in the
/system/authentication/user list.

For NETCONF transport protocols that support password authentication,
the leaf-list "user-authentication-order" is used to control whether
or not local user password authentication should be used.

In SSH, password authentication is requested by the client. Other
NETCONF transport protocols MAY also support password authentication.

When local user password authentication is requested, the NETCONF
transport looks up the user name provided by the client in the
/system/authentication/user list and verifies the password.

3.5.3. RADIUS Password Authentication

If the NETCONF server advertises the "radius-authentication" feature,
the device supports user authentication using RADIUS.

For NETCONF transport protocols that support password authentication,
the leaf-list "user-authentication-order" is used to control whether
or not RADIUS password authentication should be used.

In SSH, password authentication is requested by the client. Other
NETCONF transport protocols MAY also support password authentication.

3.6. System Control

The following operations are defined:

   set-current-datetime
   system-restart
   system-shutdown

Two protocol operations are included to restart or shut down the
system. The 'system-restart' operation can be used to restart the
entire system (not just the NETCONF server). The 'system-shutdown'
operation can be used to power off the entire system.
4. Relationship to the SNMPv2-MIB

If a device implements the SNMPv2-MIB [RFC3418], there are two objects that MAY be mapped by the implementation. See the YANG module definition in Section 6 for details. The following table lists the YANG data nodes with corresponding objects in the SNMPv2-MIB.

<table>
<thead>
<tr>
<th>YANG data node</th>
<th>SNMPv2-MIB object</th>
</tr>
</thead>
<tbody>
<tr>
<td>contact</td>
<td>sysContact</td>
</tr>
<tr>
<td>location</td>
<td>sysLocation</td>
</tr>
</tbody>
</table>

5. IANA Crypt Hash YANG Module

This YANG module references [RFC1321], [IEEE-1003.1-2008], and [FIPS.180-4.2012].

The initial version of this YANG module is part of RFC 7317; see the RFC itself for full legal notices."

revision 2014-08-06 {
  description
    "Initial revision.";
  reference
    "RFC 7317: A YANG Data Model for System Management";
}

typedef crypt-hash {
  type string {
    pattern
      'S0$.*'
      + '/S1$[a-zA-Z0-9./]{1,8}$[a-zA-Z0-9./]{22}'
      + '/S5$[a-zA-Z0-9./]{1,16}$[a-zA-Z0-9./]{43}'
      + '/S6$[a-zA-Z0-9./]{1,16}$[a-zA-Z0-9./]{86}';
  }
  description
    "The crypt-hash type is used to store passwords using a hash function. The algorithms for applying the hash function and encoding the result are implemented in various UNIX systems as the function crypt(3)."

  A value of this type matches one of the forms:

    S0$<clear text password>
    $<id>$<salt>$<password hash>
    $<id>$<parameter>$<salt>$<password hash>

  The ‘S0$’ prefix signals that the value is clear text. When such a value is received by the server, a hash value is calculated, and the string ‘$<id>$<salt>$’ or $<id>$<parameter>$<salt>$ is prepended to the result. This value is stored in the configuration data store."
If a value starting with '\$<id>$\$, where <id> is not '0', is received, the server knows that the value already represents a hashed value and stores it 'as is' in the data store.

When a server needs to verify a password given by a user, it finds the stored password hash string for that user, extracts the salt, and calculates the hash with the salt and given password as input. If the calculated hash value is the same as the stored value, the password given by the client is accepted.

This type defines the following hash functions:

<table>
<thead>
<tr>
<th>id</th>
<th>hash function</th>
<th>feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MD5</td>
<td>crypt-hash-md5</td>
</tr>
<tr>
<td>5</td>
<td>SHA-256</td>
<td>crypt-hash-sha-256</td>
</tr>
<tr>
<td>6</td>
<td>SHA-512</td>
<td>crypt-hash-sha-512</td>
</tr>
</tbody>
</table>

The server indicates support for the different hash functions by advertising the corresponding feature.

}
IANA has created an IANA-maintained YANG module called "iana-crypt-hash", based on the contents of Section 5, which will allow for new hash algorithms to be added to the type "crypt-hash". The registration procedure will be Expert Review, as defined by [RFC5226].

This document registers two URIs in the "IETF XML Registry" [RFC3688]. Following the format in RFC 3688, the following registrations have been made.

Registrant Contact: The IESG.
XML: N/A; the requested URI is an XML namespace.

Registrant Contact: The IESG.
XML: N/A; the requested URI is an XML namespace.

This document registers two YANG modules in the "YANG Module Names" registry [RFC6020].

name: iana-crypt-hash
prefix: ianach
reference: RFC 7317

name: ietf-system
prefix: sys
reference: RFC 7317

8. Security Considerations

The YANG modules defined in this memo are designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory to implement secure transport is SSH [RFC6242]. The NETCONF access control model [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the "ietf-system" YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g.,
edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

- /system/clock/timezone: This choice contains the objects used to control the time zone used by the device.
- /system/ntp: This container contains the objects used to control the Network Time Protocol servers used by the device.
- /system/dns-resolver: This container contains the objects used to control the Domain Name System servers used by the device.
- /system/radius: This container contains the objects used to control the Remote Authentication Dial-In User Service servers used by the device.
- /system/authentication/user-authentication-order: This leaf controls how user login attempts are authenticated by the device.
- /system/authentication/user: This list contains the local users enabled on the system.

Some of the readable data nodes in the "ietf-system" YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

- /system/platform: This container has objects that may help identify the specific NETCONF server and/or operating system implementation used on the device.
- /system/authentication/user: This list has objects that may help identify the specific user names and password information in use on the device.

Some of the RPC operations in the "ietf-system" YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. These are the operations and their sensitivity/vulnerability:

- set-current-datetime: Changes the current date and time on the device.
- system-restart: Reboots the device.
- system-shutdown: Shuts down the device.
Since this document describes the use of RADIUS for purposes of authentication, it is vulnerable to all of the threats that are present in other RADIUS applications. For a discussion of such threats, see [RFC2865] and [RFC3162], and Section 4 of [RFC3579].

This document provides configuration parameters for SSH’s "publickey" and "password" authentication mechanisms. Section 9.4 of [RFC4251] and Section 11 of [RFC4252] discuss security considerations for these mechanisms.

The "iana-crypt-hash" YANG module defines a type "crypt-hash" that can be used to store MD5 hashes. [RFC6151] discusses security considerations for MD5. The usage of MD5 is NOT RECOMMENDED.
