LISP Internet Groper (LIG)  
draft-ietf-lisp-lig-06

Abstract

A simple tool called the LISP Internet Groper or 'lig' can be used to query the LISP mapping database. This draft describes how it works.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 12, 2012.

1. Introduction

LISP [LISP] specifies an architecture and mechanism for replacing the addresses currently used by IP with two separate name spaces: Endpoint IDs (EIDs), used within sites, and Routing Locators (RLOCs), used on the transit networks that make up the Internet infrastructure. To achieve this separation, the Locator/ID Separation Protocol (LISP) defines protocol mechanisms for mapping from EIDs to RLOCs. In addition, LISP assumes the existence of a database to store and propagate those mappings globally. Several such databases have been proposed, among them: LISP-CONS [CONS], LISP-NERD [NERD], and LISP+ALT [ALT], with LISP+ALT being the system that is currently being implemented and deployed on the pilot LISP network.

In conjunction with the various mapping systems, there exists a network based API called LISP Map-Server [LISP-MS]. Using Map-Resolvers and Map-Servers allows LISP sites to query and register into the database in a uniform way independent of the mapping system used. Sending Map-Requests to Map-Resolvers provides a secure mechanism to obtain a Map-Reply containing the authoritative EID-to-RLOC mapping for a destination LISP site.

The 'lig' is a manual management tool to query the mapping database. It can be run by all devices which implement LISP, including ITRs, ETRs, PITRs, PETRs, Map-Resolvers, Map-Servers, and LISP-ALT routers, as well as by a host system at either a LISP-capable or non-LISP-capable site.

The mapping database system is typically a public database used for wide-range connectivity across Internet sites. The information in the public database is purposely not kept private so it can be generally accessible for public use.
2. Definition of Terms

Map-Server: a network infrastructure component which learns EID-to-RLOC mapping entries from an authoritative source (typically, an ETR, though static configuration or another out-of-band mechanism may be used). A Map-Server advertises these mappings in the distributed mapping database.

Map-Resolver: a network infrastructure component which accepts LISP Encapsulated Map-Requests, typically from an ITR, quickly determines whether or not the destination IP address is part of the EID namespace; if it is not, a Negative Map-Reply is immediately returned. Otherwise, the Map-Resolver finds the appropriate EID-to-RLOC mapping by consulting the distributed mapping database system.

Routing Locator (RLOC): the IPv4 or IPv6 address of an egress tunnel router (ETR). It is the output of a EID-to-RLOC mapping lookup. An EID maps to one or more RLOCs. Typically, RLOCs are numbered from topologically-aggregatable blocks that are assigned to a site at each point to which it attaches to the global Internet. Thus, the topology is defined by the connectivity of provider networks and RLOCs can be thought of as PA addresses. Multiple RLOCs can be assigned to the same ETR device or to multiple ETR devices at a site.

Endpoint ID (EID): a 32-bit (for IPv4) or 128-bit (for IPv6) value used in the source and destination address fields of the first (most inner) LISP header of a packet. The host obtains a destination EID the same way it obtains a destination address today, for example through a DNS lookup. The source EID is obtained via existing mechanisms used to set a host’s "local" IP address. An EID is allocated to a host from an EID-prefix block associated with the site where the host is located. An EID can be used by a host to refer to other hosts. EIDs must not be used as LISP RLOCs. Note that EID blocks may be assigned in a hierarchical manner, independent of the network topology, to facilitate scaling of the mapping database. In addition, an EID block assigned to a site may have site-local structure (subnetting) for routing within the site; this structure is not visible to the global routing system.

EID-to-RLOC Cache: a short-lived, on-demand table in an ITR that stores, tracks, and is responsible for timing-out and otherwise validating EID-to-RLOC mappings. This cache is distinct from the full "database" of EID-to-RLOC mappings, it is dynamic, local to the ITR(s), and relatively small while the database is distributed, relatively static, and much more global in scope.
EID-to-RLOC Database: a global distributed database that contains all known EID-prefix to RLOC mappings. Each potential ETR typically contains a small piece of the database: the EID-to-RLOC mappings for the EID prefixes "behind" the router. These map to one of the router's own, globally-visible, IP addresses.

Encapsulated Map-Request (EMR): an EMR is a Map-Request message which is encapsulated with another LISP header using UDP destination port number 4341. It is used so an ITR, PITR, or a system initiating a 'lig' command can get the Map-Request to a Map-Resolver by using locater addresses. When the Map-Request is decapsulated by the Map-Resolver it will be forwarded on the ALT network to the Map-Server that has injected the EID-prefix for a registered site. The Map-Server will then encapsulate the Map-Request in a LISP packet and send it to an ETR at the site. The ETR will then return an authoritative reply to the system that initiated the request. See [LISP] for packet format details.

Ingress Tunnel Router (ITR): An ITR is a router which accepts an IP packet with a single IP header (more precisely, an IP packet that does not contain a LISP header). The router treats this "inner" IP destination address as an EID and performs an EID-to-RLOC mapping lookup. The router then prepends an "outer" IP header with one of its globally-routable RLOCs in the source address field and the result of the mapping lookup in the destination address field. Note that this destination RLOC may be an intermediate, proxy device that has better knowledge of the EID-to-RLOC mapping closer to the destination EID. In general, an ITR receives IP packets from site end-systems on one side and sends LISP-encapsulated IP packets toward the Internet on the other side.

Egress Tunnel Router (ETR): An ETR is a router that accepts an IP packet where the destination address in the "outer" IP header is one of its own RLOCs. The router strips the "outer" IP header and forwards the packet based on the next IP header found. In general, an ETR receives LISP-encapsulated IP packets from the Internet on one side and sends decapsulated IP packets to site end-systems on the other side. ETR functionality does not have to be limited to a router device. A server host can be the endpoint of a LISP tunnel as well.

Proxy ITR (PITR): A PITR is also known as a PTR is defined and described in [INTERWORK], a PITR acts like an ITR but does so on behalf of non-LISP sites which send packets to destinations at LISP sites.
Proxy ETR (PETR): A PETR is defined and described in [INTERWORK], a PETR acts like an ETR but does so on behalf of LISP sites which send packets to destinations at non-LISP sites.

xTR: A xTR is a reference to an ITR or ETR when direction of data flow is not part of the context description. xTR refers to the router that is the tunnel endpoint. Used synonymously with the term "Tunnel Router". For example, "An xTR can be located at the Customer Edge (CE) router", meaning both ITR and ETR functionality is at the CE router.

Provider Assigned (PA) Addresses: PA addresses are an address block assigned to a site by each service provider to which a site connects. Typically, each block is sub-block of a service provider Classless Inter-Domain Routing (CIDR) [RFC4632] block and is aggregated into the larger block before being advertised into the global Internet. Traditionally, IP multihoming has been implemented by each multi-homed site acquiring its own, globally-visible prefix. LISP uses only topologically-assigned and aggregatable address blocks for RLOCs, eliminating this demonstrably non-scalable practice.
3. Basic Overview

When the lig command is run, a Map-Request is sent for a destination
EID. When a Map-Reply is returned, the contents are displayed to the
user. The information displayed includes:

- The EID-prefix for the site the queried destination EID matches.
- The locator address of the Map Replier.
- The locator-set for the mapping entry which includes the locator
  address, up/down status, priority, and weight of each locator.
- An round-trip-time estimate for the Map-Request/Map-Reply
  exchange.

A possible syntax for a lig command could be:

```
lig <destination> [source <source>] [to <map-resolver>]
```

Parameter description:

<destination>: is either a Fully Qualified Domain Name or a
destination EID for a remote LISP site.

source <source>: is an optional source EID to be inserted in the
"Source EID" field of the Map-Request.

to <map-resolver>: is an optional Fully Qualified Domain Name or
RLOC address for a Map-Resolver.

The lig utility has two use cases. The first being a way to query
the mapping database for a particular EID. And the other to verify
if a site has registered successfully with a Map-Server.

The first usage has already been described. Verifying registration
is called "ligging yourself". What occurs is in the lig initiator, a
Map-Request is sent for one of the EIDs for the lig initiator’s site.
The Map-Request is then returned to one of the ETRs for the lig
initiating site. In response to the Map-Request, a Map-Reply is sent
back to the locator address of the lig initiator (note the Map-Reply
could be sent by the lig initiator). That Map-Reply is processed and
the mapping data for the lig initiating site is displayed for the
user. Refer to the syntax in section Section 4.1 for an
implementation of "ligging yourself". However, for host-based
implementations within a LISP site, "lig self" is less useful since
the host may not have an RLOC to receive a Map-Reply with. But, lig
can be used in a non-LISP site as well as from infrastructure hosts to get mapping information.
4. Implementation Details

4.1. LISP Router Implementation

The cisco LISP prototype implementation has support for lig for IPv4 and IPv6. The command line description is:

```
lig <dest-eid> [source <source-eid>] [to <mr>] [count <1-5>]
```

This command initiates the LISP Internet Groper. It is similar to the DNS analogue ‘dig’ but works on the LISP mapping database. When this command is invoked, the local system will send a Map-Request to the configured Map-Resolver. When a Map-Reply is returned, its contents will be displayed to the user. By default, up to 3 Map-Requests are sent if no Map-Reply is returned but once a Map-Reply is returned no other Map-Requests are sent. The destination can take a DNS name, or an IPv4 or IPv6 EID address. The <source-eid> can be one of the EID addresses assigned to the site in the default VRF. When <mr> is specified, then the Map-Request is sent to the address. Otherwise, the Map-Request is sent to a configured Map-Resolver. When a Map-Resolver is not configured then the Map-Request is sent on the ALT network if the local router is attached to the ALT. When "count <1-5>" is specified, 1, 2, 3, 4, or 5 Map-Requests are sent.

Some sample output:

```
router# lig abc.example.com
Send map-request to 10.0.0.1 for 192.168.1.1 ...
Received map-reply from 10.0.0.2 with rtt 0.081468 secs

Map-cache entry for abc.example.com EID 192.168.1.1:
Locator          Uptime    State  Priority/Weight  Packets In/Out
10.0.0.2         13:59:59  up     1/100            0/14

Using lig to "lig yourself" is accomplished with the following syntax:

```
lig {self | self6} [source <source-eid>] [to <mr>] [count <1-5>]
```

Use this command for a simple way to see if the site is registered with the mapping database system. The destination-EID address for the Map-Request will be the first configured EID-prefix for the site (with the host-bits set to 0). For example, if the site's EID-prefix
is 192.168.1.0/24, the destination-EID for the Map-Request is 192.168.1.0. The source-EID address for the Map-Request will also be 192.168.1.0 (in this example) and the Map-Request is sent to the configured Map-Resolver. If the Map-Resolver and Map-Server are the same LISP system, then the "lig self" is testing if the Map-Resolver can "turn back a Map-Request to the site". If another Map-Resolver is used, it can test that the site’s EID-prefix has been injected into the ALT infrastructure in which case the lig Map-Request is processed by the Map-Resolver, propagated through each ALT router hop to the site’s registered Map-Server. Then the Map-Server returns the Map-Request to the originating site. In which case, an xTR at the originating site sends a Map-Reply to the source of the Map-Request (could be itself or another xTR for the site). All other command parameters are described above. Using "lig self6" tests for registering of IPv6 EID- prefixes.

Some sample output for ligging yourself:

router# lig self
Send loopback map-request to 10.0.0.1 for 192.168.2.0 ...
Received map-reply from 10.0.0.3 with rtt 0.001592 secs

Map-cache entry for EID 192.168.2.0:
192.168.2.0/24, uptime: 00:00:02, expires: 23:59:57
    via map-reply, self
Locator       Uptime    State  Priority/Weight  Packets In/Out
10.0.0.3      00:00:02  up     1/100            0/0

router# lig self6
Send loopback map-request to 10.0.0.1 for 2001:db8:1:: ...
Received map-reply from 10::1 with rtt 0.044372 secs

Map-cache entry for EID 192:168:1::
2001:db8:1::/48, uptime: 00:00:01, expires: 23:59:58
    via map-reply, self
Locator       Uptime    State  Priority/Weight  Packets In/Out
10.0.0.3      00:00:01  up     1/100            0/0
2001:db8:ffff::1 00:00:01  up     2/0              0/0

4.2. Public Domain Host Implementation

There is a public domain implementation that can run on any x86 based system. The only requirement is that the system that initiates lig must have an address assigned from the locator namespace.
lig [-d] <eid> -m <map-resolver> [-c <count>] [-t <timeout>]

Parameter description:

-d: prints additional protocol debug output.

-eid>: is the destination EID or FQDN of a LISP host.

-m <map-resolver>: is the RLOC address or FQDN of a Map-Resolver.

-c <count>: the number of Map-Requests to send before the first Map-
Reply is returned. The default value is 3. The range is from 1 to 5.

-t <timeout>: the amount of time, in seconds, before another Map-
Request is sent when no Map-Reply is returned. The default value is 2 seconds. The range is from 1 to 5.

Some sample output:

% lig xyz.example.com -m 10.0.0.1
Send map-request to 10.0.0.1 for 192.168.1.1 ...
Received map-reply from 10.0.0.2 with rtt 0.04000 sec

Mapping entry for EID 192.168.1.1:
192.168.1.0/24, record ttl: 60
 Locator State Priority/Weight
 10.0.0.1 up 1/25
 10.0.0.2 up 1/25
 10.0.0.3 up 1/25
 10.0.0.4 up 2/25

The public domain implementation of lig is available at http://github.com/davidmeyer/lig.
5. Testing the ALT

There are cases where a Map-Reply is returned from a lig request but the user doesn't really know how much of the mapping infrastructure was tested. There are two cases to consider, avoiding the ALT and traversing the ALT.

When an ITR sends a lig request to its Map-Resolver for a destination-EID, the Map-Resolver could also be configured as a Map-Server. And if the destination-EID is for a site that registers with this Map-Server, the Map-Request is sent to the site directly without testing the ALT. This occurs because the Map-Server is the source of the advertisement for the site’s EID-prefix. So if the map-reply is returned to the lig requesting site, you cannot be sure that other sites can reach the same destination-EID.

If a Map-Resolver is used that is not a Map-Server for the EID-prefix being sought, then the ALT infrastructure can be tested. This test case is testing the functionality of the Map-Resolver, traversal of the ALT (testing BGP-over-GRE), and the Map-Server.

It is recommended that users issue 2 lig requests, each of which send Map-Requests to different Map-Resolvers.

The network can have a LISP-ALT router deployed as a "ALT looking-glass" node. This type of router has BGP peering sessions with other ALT routers where it does not inject any EID-prefixes into the ALT but just learns ones advertised by other ALT routers and Map-Servers. This router is configured as a Map-Resolver. Lig users can point to the ALT looking-glass router for Map-Resolver services via the "to <map-resolver>" parameter on the lig command. The ALT looking-glass node can be used to lig other sites as well as your own site. When the ALT looking-glass is used as a Map-Resolver, you can be assured the ALT network is being tested.
6. Future Enhancements

When negative Map-Replies have been further developed and implemented, lig should be modified appropriately to process and clearly indicate how and why a negative Map-Reply was received. Negative Map-Replies could be sent in the following cases, the lig request was initiated for a non-EID address or the Map-Request initiated by lig request is being rejected due to rate-limiting on the replier.
7. Deployed Network Diagnostic Tools

There is an web-based interface to do auto-polling with lig on the back-end for most of the LISP sites on the LISP test network. The web-page can be accessed at http://www.lisp4.net/status.

There is a LISP site monitoring web-based interface that can be found at http://www.lisp4.net/lisp-site.

At http://baldomar.ccaba.upc.edu/lispmon, written by the folks at UPC, shows a geographical map indicating where each LISP site resides.
8. Security Considerations

The use of lig does not affect the security of the LISP infrastructure as it is simply a tool that facilitates diagnostic querying. See [LISP], [ALT], and [LISP-MS] for descriptions of the security properties of the LISP infrastructure.

Lig provides easy access to the information in the public mapping database. Therefore, it is important to protect the mapping information for private use. This can be provided by disallowing access to specific mapping entries or to place such entries in a private mapping database system.
9. IANA Considerations

This document makes no request of the IANA.
